PPWB COMMITTEE ON HYDROLOGY**

**NATURAL
FLOW**

**SWAN RIVER
AT SASKATCHEWAN – MANITOBA BOUNDARY**

PREPARED BY:

**HYDROLOGY DIVISION
PRAIRIE FARM REHABILITATION ADMINISTRATION
AGRICULTURE CANADA**

SYNOPSIS

The average annual natural flow of Swan River at the Saskatchewan-Manitoba boundary is 184 100 dam³. Average annual consumptive water use in the Saskatchewan portion of the basin now amounts to approximately 117 dam³, 0.06% of the average annual natural flow.

The present (1983) level of consumptive use in the Saskatchewan portion of the Swan River basin would not have exceeded Saskatchewan's 50% share of the natural flow at the Saskatchewan-Manitoba boundary at any time during the 71-year period 1912-13 to 1982-83. In fact, Saskatchewan would have used an annual maximum of only 0.75% of the natural flow (corresponds to the water balance period 1963-64). The average annual quantity of water which would have been delivered to Manitoba in excess of 50% of natural flow would have amounted to approximately 91 900 dam³.

The existing hydrometric network does not provide adequate hydrometric data for calculating the natural flow of Swan River at the Saskatchewan-Manitoba boundary. However, an accurate estimate of natural flow at the boundary is not required until water uses in the Saskatchewan portion of the basin become significant. Monitoring of apportionment is not required at the present time because the uses in the Saskatchewan portion of the basin are negligible.

---	--	----

The Swan River natural flow study is one of a series of natural flow studies conducted for the Prairie Provinces Water Board. Following completion of the Prairie Provinces Water Board's study on determination of natural flow of the North Saskatchewan, South Saskatchewan, Saskatchewan, Churchill, and Qu'Appelle River basins in 1977, the Board agreed to have other interprovincial basins studied to determine if monitoring of flow for apportionment purposes might be required. Eighteen interprovincial basins were initially identified and assigned a priority. (Two additional basins, Beaver River and Overflowing River, were subsequently added to the list.) The Board agreed that the basins would be studied in order of priority as funds and time became available.

This report entitled 'Natural Flow, Swan River at Saskatchewan-Manitoba Boundary' describes the basin geography, water use within the basin, and the derivation of historic natural flows at the Saskatchewan-Manitoba boundary. The present (1983) level of use is analyzed in conjunction with natural flows to determine the potential for apportionment deficits now and in the foreseeable future. The procedure to be used for the future calculation of natural flow is also provided, and the adequacy of the existing hydrometric network for the determination of natural flow at the interprovincial boundary is assessed.

Swan River originates in eastern Saskatchewan, immediately west of the Porcupine Hills, approximately 75 km north of the Town of Norquay, Saskatchewan (see Figure 1). The river flows in a southerly direction for approximately 80 km and then, near the Town of Norquay, it swings in an easterly direction for 30 km before passing into Manitoba. After reaching Manitoba, the river takes a northeasterly course for approximately 25 km to the Town of Swan River. The river continues flowing in a northeasterly direction and eventually discharges into Swan Lake approximately 55 km from the Town of Swan River.

The topography of the area provides reasonably well drained conditions throughout the basin (i.e. effective to gross drainage area ratio is in the order of 0.85). However, in certain portions of the basin, runoff is retarded by several small lakes. Consequently, the unit runoff in these areas is probably somewhat lower than for the rest of the basin.

The gross and effective drainage areas of the Swan River basin at the Saskatchewan-Manitoba boundary are 3 397 km² and 2 831 km², respectively. A minor portion of the runoff at the boundary originates in Manitoba from an area having a gross drainage area of 227 km² and an effective drainage area of 212 km². Also, a minor tributary of the Swan

River originates in Saskatchewan and flows into Manitoba, joining the Swan River between the interprovincial boundary and the gauging station Swan River at Swan River (05LE001). The drainage area (effective drainage area equals gross drainage area) of the Saskatchewan portion of this tributary is 58.8 km². A table of gross and effective drainage areas^(1,2) for key points in the basin is provided in Figure 1.

Swan River is classified as a perennial stream. Snowmelt in the spring contributes to high flows which eventually give way to a generally diminishing base flow resulting from groundwater contribution which persists throughout the remainder of the year. The median and mean annual natural runoff volumes of Swan River at the Saskatchewan-Manitoba boundary are 161 900 dam³ and 184 100 dam³, respectively. These values were determined from the array of natural flows at the interprovincial boundary as presented in Appendix B, Table B-7.

No major water use projects are located within the effective drainage area in the Saskatchewan portion of the Swan River basin. However, the Bear Head Creek Project (file number 13931), constructed by Ducks Unlimited in 1979, is sufficiently large that the project was simulated separately to determine the evaporative water use of the project. Information on licensed minor water use projects was obtained from the Saskatchewan Water Corporation. Unauthorized water use projects were identified on aerial photographs and then investigated during an October, 1984 field trip. This field assessment involved quantitatively estimating the amount of use (including evaporation losses) for all man-made storages and interviewing local residents to determine the period of time each project had been in operation. All water use projects within the effective drainage area of the Swan River basin at the Saskatchewan-Manitoba boundary are included in Table 1.

Several licensed and unauthorized minor water use projects are located within the effective drainage area in the Manitoba portion of the Swan River basin. Information on licensed water use projects was obtained from the Water Resources Branch of the Manitoba Department of Natural Resources. Unauthorized water use projects were identified on aerial photographs and assessed during the October, 1984 field investigation. In addition, effluent from the Town of Swan River sewage system is

discharged into the Swan River. (The town obtains its water from wells.) Monthly effluent discharges from the Town of Swan River sewage system were estimated from water consumption records and historic system operation. Prior to 1954, no sewage was discharged into the Swan River by the Town of Swan River. Between 1954 and 1975, the sewage treatment plant utilized an activated sludge process and was assumed to have discharged effluent uniformly throughout the year. Since 1975, the Town of Swan River has used aerobic lagoons for sewage treatment. Effluent discharge from these lagoons is assumed to have occurred twice a year in the months of May and October.

An itemized list of all historic water uses within the effective drainage area of the Swan River basin is provided in Table 1.

* Estimated average annual net depletion to streamflow, including evaporation.

Natural flow, the quantity of water which would have been recorded under natural conditions (i.e. prior to the effect of human interference or intervention), was derived by using the Project Depletion Method⁽³⁾ to adjust recorded flow. The natural flows were transferred, as appropriate, from the gauging station Swan River at Swan River (05LE001) to the gauging station Swan River near Minitonas (05LE006) and the resultant partial array was extended to cover the 72-year historic period 1912 to 1983. The natural flows were then transferred to the Saskatchewan-Manitoba boundary using a procedure based on drainage area ratios.

The first hydrometric gauging station in the basin, Swan River at Swan River (05LE001), was established in 1912 and operated for 25 years until 1936. It was reactivated in 1950 and operated for 11 years until 1960. In 1960, the station was moved 18 km downstream and since then, it has been operated as the hydrometric gauging station Swan River near Minitonas (05LE006). Another hydrometric gauging station, Swan River near Norquay (05LE008), was established upstream of the Saskatchewan-Manitoba boundary in 1965 and is also still in operation. The arrays of recorded monthly mean flows for these three stations are shown in Appendix B, Tables B-1, B-2 and B-3.

Historic upstream minor water uses within the effective drainage area of the Swan River basin, as shown in Table 1, were determined on an annual basis as a function of estimated water use (including evaporation) and available inflow. The estimated annual water uses varied from year to year because of the variable net evaporation and the limitation of restricting annual water use in any given year to available flow. All of the water use projects presented in Table 1 lie within the effective drainage area of the Swan River basin above the most downstream hydrometric gauging station, Swan River near Minitonas (05LE006) and thus were used in the natural flow calculations.

The variable estimated annual water uses for all projects located above each of the three hydrometric gauging stations were added to the appropriate recorded monthly mean flows of the respective gauging stations. The resulting natural monthly mean flows for the station 05LE001 were transferred downstream to the hydrometric station 05LE006 using the effective drainage area ratio of 1.045 to produce an array of natural monthly mean flows of Swan River near Minitonas (05LE006) for the years 1912 to 1936 and 1950 to 1983. Natural monthly mean flows for periods of missing record in the period 1912 to 1983 were estimated from recorded and natural flows in adjacent drainage basins, and from precipitation records for the nearest long-term climate station (Yorkton).

For the months March to November inclusive, missing natural monthly mean flows of Swan River near Minitonas (05LE006) were estimated using the regression equations presented in Appendix B, Table B-4. Priorities were assigned to the regression equations on the basis of the adjusted (to account for degrees of freedom) coefficient of correlation, the adjusted standard error of estimate, the magnitude of the intercept, and the overall hydrologic validity of each equation. The regression equation assigned priority No. 1 was used to estimate as many missing values as possible, then the regression equations assigned priorities No. 2, 3 and 4 were used to estimate values which had not been estimated from higher priority regression equations. The variables used in these

regression equations were selected on the basis of hydrologic similarity and their potential for providing estimates of flow for periods of missing data.

For the months December to February inclusive, missing natural flows of Swan River near Minitonas (05LE006) were derived from graphical regression analysis with natural flows of Assiniboine River at Brandon (05MH001) for the corresponding period. (The station Assiniboine River at Brandon [05MH001] was the only station in the vicinity that had recorded winter flows which covered the corresponding period of missing data for the base station, Swan River near Minitonas [05LE006].) The summed winter flow for the missing months December to February were determined from the graphical regression analysis. Based on the recorded period 1961-83, the monthly mean flow in each individual month was then calculated as a fixed proportion of the estimated summed winter flow; December as 50%, January as 28%, and February as 22% of the summed winter flow.

Natural flows of Swan River at the Saskatchewan-Manitoba boundary were determined for all months of the period 1974-83, for March to October of 1965-73 and for November and December of 1973 by interpolating between calculated natural flows for the hydrometric gauging stations Swan River near Minitonas (05LE006) and Swan River near Norquay (05LE008) using the equation:

$$\begin{aligned} Q_1 &= Q_2 + \frac{A_1 - A_2}{A_3 - A_2} (Q_3 - Q_2) \\ &= 0.4156 Q_2 + 0.5844 Q_3 \end{aligned}$$

where:

Q_1 = Natural monthly mean flow (m^3/s) of Swan River at the Saskatchewan-Manitoba boundary,

Q_2 = Natural monthly mean flow (m^3/s) of Swan River near Norquay (05LE008),

Q_3 = Natural monthly mean flow (m^3/s) of Swan River near Minitonas (05LE006),

A_1 = Effective drainage area (km^2) of Swan River at the Saskatchewan-Manitoba boundary,

A_2 = Effective drainage area (km^2) of Swan River near Norquay (05LE008), and

A_3 = Effective drainage area (km^2) of Swan River near Minitonas (05LE006).

For all other months in the period 1912-83, natural flows of Swan River at the Saskatchewan-Manitoba boundary were determined using only the natural flows derived for the hydrometric gauging station Swan River near Minitonas (05LE006). It was felt that using only this station to estimate natural flows at the boundary provided better estimates than could have been obtained by also utilizing the upstream station (i.e. 05LE008) whereby estimates of natural flow at the boundary would have been calculated as before by interpolation between the two stations 05LE008 and 05LE006. (An additional inherent uncertainty would have been introduced by the use of estimated monthly flows for 05LE008.) However, the upstream station was used indirectly. Twelve linear relationships between the ratio of average monthly runoff for the hydrometric station Swan River near Norquay (05LE008) to average monthly runoff for the hydrometric station Swan River near Minitonas (05LE006) were developed based on the overlapping period of record 1965-83. These monthly relationships were substituted into the foregoing equation and the equation was reduced to simply a function of Q_3 having the following monthly coefficients:

January	- 0.922	July	- 0.869
February	- 0.972	August	- 0.870
March	- 0.920	September	- 0.991
April	- 0.749	October	- 0.943
May	- 0.815	November	- 0.929
June	- 0.857	December	- 0.933

The simplified monthly relationships were used to transfer natural flows derived for the hydrometric gauging station Swan River near Minitonas (05LE006) to the Saskatchewan-Manitoba boundary. The resulting

natural monthly mean flows derived for Swan River at the Saskatchewan-Manitoba boundary for the water years 1912-13 to 1982-83 are shown in Appendix B, Table B-7. Caution should be exercised by users who may wish to utilize this data base in conducting other studies. Such data users should recognize the limitations of the estimates which were made. The estimates have been published because it is unlikely that better estimates of streamflow can be generated based on the present level of hydrologic expertise in estimating missing streamflow data. These estimates provide an adequate means of evaluating the effect of present consumptive water use in Saskatchewan on flows of Swan River at the Saskatchewan-Manitoba boundary over the 71-year historic period 1912-13 to 1982-83.

An analysis was made to determine whether present (1983) use flow of Swan River at the Saskatchewan-Manitoba boundary would have been less than 50% of the natural flow, under the terms of the 1969 Master Agreement on Apportionment, in the period 1912-13 to 1982-83. A monthly array of uses was created, assuming that the Bear Head Creek Project (file number 13931) and the current minor uses upstream of the Saskatchewan-Manitoba boundary (note: all uses are in Saskatchewan) were in existence for the entire study period. The existing water uses within the effective drainage area of the Swan River basin upstream of the interprovincial boundary were determined for the study period on an annual basis as a function of estimated water use (including evaporation) and available inflow. The estimated annual water uses varied from year to year because of the variable net evaporation and the limitation of restricting annual water use in any given year to available flow. Current water uses upstream of the Saskatchewan-Manitoba boundary were combined to form an array of monthly uses (Appendix A, Table A-2). This array of monthly uses was subtracted from the natural flows at the interprovincial boundary to produce an estimate of monthly flows (Appendix B, Table B-8) which would have been recorded at the Saskatchewan-Manitoba boundary during the period 1912-13 to 1982-83 had the present (1983) level of use been in effect for the entire period.

An array of one-half the natural flow at the interprovincial boundary was then subtracted from the array of natural flows adjusted for present use (Appendix B, Table B-8). The residual monthly flows (Appendix B, Table B-9) provide a picture of the balance-of-flow situation for Swan River over the 71-year historic period 1912-13 to 1982-83. Table B-9 indicates that Saskatchewan would have always passed at least 50% of the natural flow of Swan River at the interprovincial boundary on a monthly basis during the 71-year period. In fact, Saskatchewan would have used an annual maximum of only 0.75% of the natural flow (corresponds to the water balance period 1963-64) under the present (1983) level of development. Thus, Manitoba would have received an average annual volume of approximately 91 900 dam³ in excess of its 50% share.

At some time in the future, the procedure for determining whether both provinces have received their share of the natural flow may become more complex depending upon the magnitude and location of water use projects because a portion of the basin drains from Manitoba into Saskatchewan. However, as the portion of the basin which drains from Manitoba into Saskatchewan is relatively small, the need for a complex methodology is unlikely. If required, the implementation of a methodology for monitoring the apportionment of flow will be made by the appropriate jurisdictions using the methodology presented in a report⁽⁴⁾ currently being prepared for the PPWB by the Committee on Hydrology. This methodology has been developed specifically as a base for providing a mutual resolution of flow apportionment in such situations (i.e. apportionment of flows in westward flowing tributaries of eastward flowing streams).

PROCEDURE FOR FUTURE CALCULATION OF NATURAL FLOW

If it becomes necessary to formally monitor the apportionment of streamflow in the Swan River basin, natural flow calculations would have to be performed on a regular basis to ensure that Manitoba receives its share of the flow. Natural flows of Swan River would be computed using the Project Depletion Method, based on the generalized equation:

$$Q_{\text{Nat.}} = Q_{\text{Rec.}} + \text{N.D.}$$

where:

- $Q_{\text{Nat.}}$ is the natural flow at the hydrometric station,
- $Q_{\text{Rec.}}$ is the recorded flow at the hydrometric station, and
- N.D. is the net depletion of streamflow at upstream projects.

The net depletion of streamflow at a project may be computed as the sum of:

1. water withdrawal for human or livestock use, less the portion of this withdrawal which is returned to the stream or reservoir,
2. net evaporation (gross evaporation minus precipitation) from the reservoir, and
3. change in reservoir storage over the specified time interval; an increase in storage is considered a positive (+) net depletion while a decrease in storage is considered a negative (-) net depletion.

The computed natural flows at the interprovincial boundary to be used for monitoring flow apportionment should be determined using the methodology developed in this section. However, the methodology may have to be modified as necessary to account for any further developments in the basin or changes to the hydrometric network. This section describes the procedure for calculation of natural flow of Swan River at the Saskatchewan-Manitoba boundary based on current water use projects and the existing hydrometric network. The procedure has been simplified because of the insignificance of the current water use in relation to runoff. When water use in the Swan River basin becomes significant, a more complex procedure such as the one used to calculate historic natural flows should be considered.

Recorded flows of Swan River near Minitonas (05LE006) and Swan River near Norquay (05LE008) are first adjusted for net depletions to stream-flow by upstream projects. The resultant natural flows are then used to estimate the natural flow at the Saskatchewan-Manitoba boundary. A more detailed explanation of the entire process is provided in the following subsections.

1) Net Depletions to Natural Flow

a) Swan River near Minitonas (05LE006)

Flow of Swan River near Minitonas (05LE006) is affected by all water uses within the effective drainage area of the Swan River basin above the station including effluent discharges from the Town of Swan River sewage lagoons, minor water uses in both Saskatchewan and Manitoba and water use by major projects such as the Ducks Unlimited Bear Head Creek Project (file number 13931). The effluent discharges increase the flow, while the other water uses decrease the flow. The effects of these "uses" must be considered in determining the flow that would have occurred under natural conditions.

i) Town of Swan River Sewage Effluent Discharges

The Town of Swan River presently obtains its water supply from groundwater through two wells on the northeast town limits.

Sewage is then treated in lagoons located approximately two kilometres northeast of the town limits and discharged twice annually into the Swan River. These discharges are made after May 15th and prior to November 1st, provided that effluent B.O.D. levels are approved by the Manitoba Environment and the Workplace Safety and Health Department.

Estimation of effluent discharge to Swan River is based on the following assumptions:

1. Nine percent of the annual groundwater volume pumped from town wells is used for backwashing and is added directly to the sanitary sewage system which discharges into the sewage lagoons.
2. The balance of the water is treated in the Town of Swan River water treatment plant and eighty percent of the treated water is assumed to be eventually discharged to the sewage lagoons.
3. The lagoons are assumed to discharge twice a year in the months of May and October. These discharges are assumed to be of equal volume equivalent to one-half the annual effluent volume.

As an example, 397 dam³ of water was pumped from the Town of Swan River wells in 1983 and of this volume, 36 dam³ was used for backwashing and then discharged directly to the lagoons. Of the remaining 361 dam³ of treated water, eighty percent was assumed to pass through the sewage system as wastewater to be treated in the sewage lagoons. From the annual combined backwash and wastewater volume of 324.8 dam³, equal discharges from the lagoons of 162.4 dam³ in the months of May and October were assumed to reach the Swan River. Consequently, these volumes were deducted (i.e. by adding a negative value) from the recorded flow in the calculation of natural flow.

ii) Minor Water Uses

All estimated annual net depletions by existing water use projects (i.e. all projects shown in Table 1 excluding project numbers 3, 5 and 9) within the effective drainage area of the Swan River basin above the gauging station Swan River near Minitonas (05LE006) are considered. Domestic projects are assumed to deplete streamflow during

the month of major spring runoff. Pumped irrigation projects (project numbers 2, 6, 13 and 14) are assumed to use water uniformly throughout the summer months June to August. The wildlife project (project number 1) is assumed to deplete streamflow throughout the year, but because of its relatively large size, this project is given special consideration. However, before its effect on natural flow is determined, partial natural flows are calculated using all of the other water uses, including sewage effluent discharge.

Table 2 illustrates the procedure for calculating partial natural monthly mean flows of Swan River near Minitonas (05LE006) for 1983 by adding the minor water uses and effluent discharge depletions to the recorded flow.

* Summation of recorded flow, minor use depletion and effluent discharge depletion.

iii) Bear Head Creek Project (project number 1)

Ducks Unlimited constructed the Bear Head Creek Project at SE19-32-29-W1 in 1979 to control water levels on an existing lake in order to promote the production of migratory waterfowl. Since this project raises the level of an existing lake, the net depletion of

streamflow by this project is calculated as the difference between an estimate of the natural outflow from the lake without controls and the outflow from the project with controls in place.

To calculate the net depletion of this project, reservoir simulations must be performed to calculate both the outflow under natural conditions and the outflow under present conditions. Inflow to the project under both conditions can be estimated by applying the effective drainage area ratio of 0.0276 to the partial natural flows for Swan River near Minitonas (05LE006). Partial natural flows are determined as previously described by accounting for the Town of Swan River effluent discharges and the minor uses above the station excluding the Bear Head Creek Project.

The estimated natural monthly inflows are routed through the reservoir, accounting for monthly reservoir demands. (The only demand on this project is the evaporation losses from the lake surface area. Net evaporation at the project is estimated by transferring precipitation and gross evaporation from Yorkton using transfer factors of 1.118 and 0.830, respectively.) The net depletion by the Bear Head Creek Project is calculated as the difference between the estimated natural outflow from the lake and the estimated spills from the constructed project. This net depletion is then added to the partial natural flow of Swan River near Minitonas (05LE006) in order to obtain the final natural flows for that gauging station. Table 3 illustrates the procedure for calculating natural monthly mean flows of Swan River near Minitonas (05LE006) for 1983 by adding the difference between natural outflows and project spills to the partial natural flows of Swan River near Minitonas (05LE006).

(1) From Table 2.

(2) Calculated as partial natural flow(1) multiplied by 0.0276.

(3) Estimated natural outflow from Bear Head Lake derived from reservoir simulations.

(4) Estimated project spills from Bear Head Creek Project derived from reservoir simulations.

(5) Calculated as natural outflow(3) minus project spills(4).

(6) Calculated as partial natural flow(1) plus the difference(5) between natural outflow and project spills.

b) Swan River near Norquay (05LE008)

Natural flow of Swan River near Norquay (05LE008) is affected by minor water use projects (project numbers 6, 7 and 8 shown in Table 1) within the effective drainage area of the Swan River basin above the station in Saskatchewan. Domestic projects are assumed to deplete streamflow during the first month of significant spring runoff. The pumped irrigation project (project number 6) is assumed to use water uniformly throughout the summer months June to August.

Table 4 illustrates the procedure for calculating natural monthly mean flows of Swan River near Norquay (05LE008) for 1983 by adding the minor water uses to the recorded flow.

Table 4
Natural Flow Calculations - 1983
Swan River near Norquay - 05LE008

* Summation of recorded flow and minor use depletion.

2) Transfer of Natural Flows to the Interprovincial Boundary

Natural flows of Swan River at the Saskatchewan-Manitoba boundary are determined by interpolating between estimated natural flows at the hydrometric gauging stations Swan River near Minitonas (05LE006) and Swan River near Norquay (05LE008) using the equation:

$$Q_1 = Q_2 + \frac{A_1 - A_2}{A_3 - A_2} (Q_3 - Q_2)$$

$$= 0.4156 Q_2 + 0.5844 Q_3$$

where:

Q_1 = Natural monthly mean flow (m³/s) of Swan River at the Saskatchewan-Manitoba boundary,

Q_2 = Natural monthly mean flow (m³/s) of Swan River near Norquay (05LE008),

Q_3 = Natural monthly mean flow (m³/s) of Swan River near Minitonas (05LE006),

A_1 = Effective drainage area (km^2) of Swan River at the Saskatchewan-Manitoba boundary,

A_2 = Effective drainage area (km^2) of Swan River near Norquay (05LE008), and

A_3 = Effective drainage area (km^2) of Swan River near Minitonas (05LE006).

Table 5 illustrates the procedure for transferring Swan River natural flows from the hydrometric gauging stations to the interprovincial boundary for 1983.

Table 5
Determination of Natural Flows - 1983
Swan River at Saskatchewan-Manitoba Boundary

Month	Natural Flow for 05LE008(1) (m^3/s)	Natural Flow for 05LE006(2) (m^3/s)	Natural Flow at Interprovincial Boundary(3) (m^3/s)

(1) From Table 4

(2) From Table 3

(3) 0.4156 (05LE008) + 0.5844 (05LE006)

CONCLUSIONS

1. The average annual consumptive water use in the Saskatchewan portion of the Swan River basin now represents 0.06% of the average annual natural flow of Swan River at the Saskatchewan-Manitoba boundary.
2. Under present (1983) conditions, at least 50% of the natural flow of Swan River at the Saskatchewan-Manitoba boundary would have been passed to Manitoba in all months of the 71-year period 1912-13 to 1982-83. In fact, Saskatchewan would have used an annual maximum of only 0.75% of the natural flow (corresponds to the water balance period 1963-64). The average annual quantity of water which would have been delivered to Manitoba in excess of 50% of natural flow during the 71-year period would have been approximately 91 900 dam³.
3. The existing hydrometric network is not adequate for calculating the natural flow of Swan River at the Saskatchewan-Manitoba boundary. However, an accurate estimate of natural flow at the boundary is not required until water uses in the Saskatchewan portion of the basin become significant.

RECOMMENDATIONS

1. Based on the present (1983) level of development in the Saskatchewan portion of the Swan River basin, monitoring of apportionment should not be implemented at this time.
2. If monitoring of apportionment becomes necessary, a hydrometric gauging station should be established at the Saskatchewan-Manitoba boundary.

The Swan River natural flow study was conducted by D. A. Kiely of the Hydrology Division of the Prairie Farm Rehabilitation Administration. The study was carried out under the direction of F. R. J. Martin, Manager of the Hydrology Division. The final text was reviewed by R. B. Godwin, Executive Director of the Prairie Provinces Water Board, and other members of the Committee on Hydrology.

A special note of thanks must be given to R. J. Woodvine for his helpful advice on various aspects of the study and assistance in preparing this report, to both J. C. Rakochy and the Text Processing Unit for typing the text, to W. B. Gilmer for his drafting assistance, and to K. E. Dowie for his help in assembling the final report.

Table B-4

SWAN RIVER NEAR MINITONAS - 05LE006
REGRESSION EQUATIONS USED TO ESTIMATE NATURAL MONTHLY MEAN FLOW

Month ¹	Years	Regression Equation	Correlation Coefficient	Standard Error of Estimate ³	Priority Number
March	1920-21, 1930-50	$\log Q_E = -.8950 + .7753 \log MH01$.477	61.5/1600	1
April	1912, 1930-31, 1934-43, 1948	$\log Q_E = -.8208 + 1.0734 \log MH01 + .1313 \log PGM1$.729	48.2/93.0	4
	1944-46	$Q_E^2 = 6.537 + 2.0428 MC01$.887	32.7	3
	1947, 1950	$\log Q_E = .2948 + .7656 \log MD04$.867	38.8/63.3	2
	1949	$Q_E = .364 + 2.0868 MD05 + 1.0714 MC01$.910	29.9	1
May	1912, 1937-43	$\log Q_E = -.5320 + .9296 \log MH01$.878	40.9/69.2	3
	1944-47	$\log Q_E = .6587 + .7260 \log MC01$.949	31.6/46.3	2
	1948-50	$\log Q_E = .1632 + .5782 \log MD04 + .4218 \log MD05$.973	25.6/34.4	1
June	1912, 1937-43	$\log Q_E = -.9627 + .6773 \log MH01 + .4566 \log PGM1$.743	52.1/109	2
	1944-50	$Q_E^2 = 3.926 + 1.7225 MC01$.966	32.8	1
July	1912, 1937-43	$\log Q_E = -.8968 + .7479 \log MH01 + .3347 \log PGM1$.730	57.3/134	3
	1944-47	$Q_E = 2.423 + 1.6353 MC01 + .0345 MH01$.942	47.1	2
	1948-50	$Q_E = .581 + 1.2126 MD05 + .9597 MC01$.961	34.0	1
August	1912, 1937-43	$\log Q_E = -.5499 + .7940 \log MH01$.727	54.0/118	2
	1944-49	$Q_E^2 = 1.797 + 1.2173 MC01$.886	58.6	1
September	1912, 1937-43	$\log Q_E = -.7890 + 1.0392 \log MH01$.649	65.5/190	2
	1944-49	$Q_E^2 = 1.490 + 2.5837 MC01$.895	66.0	1
October	1912, 1936-43	$\log Q_E = -.4700 + .8114 \log MH01$.652	53.0/113	3
	1944-47	$Q_E^2 = 1.997 + 2.2708 MC01$.846	56.6	2
	1948-49	$Q_E = .940 + 1.6221 MC01 + .7414 MD05$.866	27.9	1
November	1920, 1929-35	$Q_E = .113 + .4357 B6L1 + .0668 MH01$.761	70.6	3
	1936	$\log Q_E = -.2947 + .3617 \log B6L2 + .4279 \log MH01$.766	49.3/97.1	1
	1937-48	$Q_E = .340 + .1700 MH01$.682	86.9	4
	1949	$\log Q_E = -.0475 + 1.2791 \log MD05$.744	49.4/97.7	2

¹ Missing natural monthly mean flows for the months December to February were estimated using the following procedure:

- summed missing winter flows for the months December to February for the years 1920-21 and 1929-50 were estimated by a graphical regression analysis with the corresponding summed winter flows for MH01.

- estimated summed winter flow was distributed to the individual winter months using the following percentages:

December = 50% of summed winter flow
 January = 28% of summed winter flow
 February = 22% of summed winter flow

- January to March monthly flows for 1912 were estimated as the average monthly flows for the periods 1913-19, 1922-29, and 1951-83.

² The lower end of the regression line was manually adjusted to intersect the origin.

³ Standard error of estimate expressed as a percentage of mean of the dependent variable for the regressed period. For logarithmic relationships, both the lower/upper bounds are given.

LIST OF SYMBOLS

B6L1 Natural flow of Swan River near Minitonas (05LE006) in October, in m³/s.

B6L2 Natural flow of Swan River near Minitonas (05LE006) in September, in m³/s.

MC01 Recorded flow of Assiniboine River at Sturgis (05MC001), in m³/s.

MD04 Natural flow of Assiniboine River near Kamsack (05MD004), in m³/s, as presented in Table B-4 of the November, 1980 PPWB Assiniboine River natural flow report(5).

MD05 Recorded flow of Shell River near Inglis (05MD005), in m³/s.

MH01 Natural flow of Assiniboine River at Brandon (05MH001), in m³/s, as developed for the November, 1980 PPWB Assiniboine River natural flow report(5).

PGM1 Total monthly precipitation at Yorkton during specified month, in mm.

Note: 1. Shaded area denotes natural flow data derived by regression analysis as indicated in Table B-4. Caution should be exercised in using these flows.
 2. Cross-hatched area denotes natural flow data derived by transferring natural flows from Swan River at Swan River (05LE001) using an effective drainage area ratio of 1.045.

Table B-6

SWAN RIVER NEAR NORQUAY - 05LE008
NATURAL FLOW FOR RECORDED PERIOD - m³/s
